

A steering handle that writes one constant over W segments keeps exactly the part of the trajectory that is constant over W
(layer 14, $k=12$, coverage held at 12 segments in every cell)

A. Fidelity $R(W, \ell)$: observed, (predicted)
hatched = fixed by construction; 6 cells can disagree

B. Control efficiency is best at $W \approx \ell$, and ties at odd multiples
($\star$ = best width; full fidelity costs k/ℓ knobs)

C. The 6 at-risk cells, both models
mean |error| 0.053 (1.5B) / 0.045 (7B), nothing fitted
