

A steering handle that writes one constant over W segments keeps exactly the part of the trajectory that is constant over W
(layer 14, $k=12$, coverage held at 12 segments in every cell)

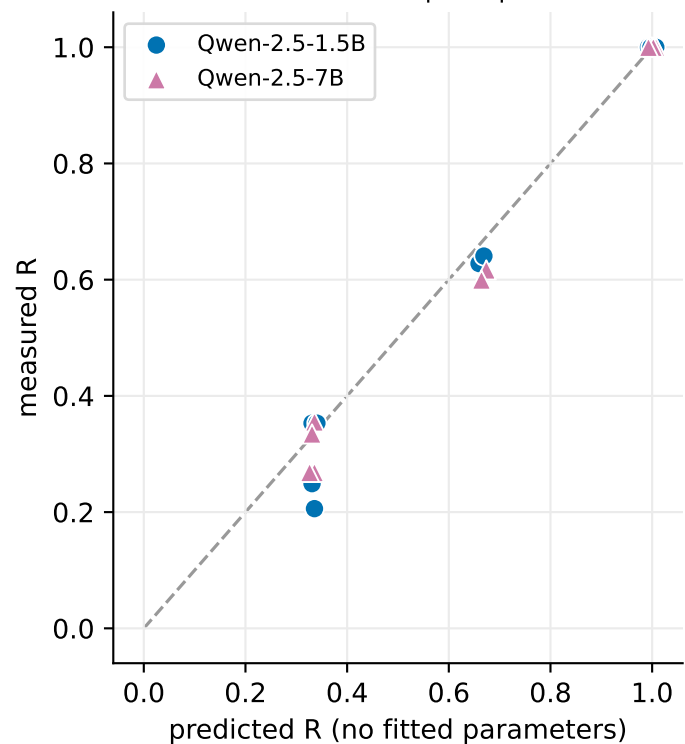

A. Fidelity $R(W, \ell)$: observed, (predicted)
11 measured cells, no fitted parameters, mean |error| = 0.029

B. Control efficiency peaks at $W \approx \ell$
(★ = best width; knobs needed for full fidelity = k/ℓ)

C. Same law in both models
6 fractional cells: mean |error| 0.053 / 0.045

fixed by construction
